Cooper pairing of fermions starts usually from the assumption that the two species forming pairs have equal populations, i.e., that their particle numbers are the same. That need not always be the case, though, and examples to the contrary are known. They concern superconducting metals, as well as dense quark matter, nuclear matter or ultra cold atoms.

The simplest case is that of a superconductor when a Zeeman term is added to the Hamiltonian. We will show that the Zeeman energy may result in breaking of anisotropy and hence in inhomogeneous superconducting ground states. Simple arguments will be presented which explain the origin of the symmetry breaking.

Experiments on CeCoIn5, and the two-dimensional organic superconductors $-(BEDTTTF)_2 \cdot Cu(NCS)_2$, $-(BETS)_2$ Cl_4 , as well as cold atoms provide strong evidence that an inhomogeneous state is forming in high magnetic fields. However, the most important realization of inhomogeneous states is found in pi junctions, which seem to be on the verge of important technical applications. We will briefly describe progress which has been made here, based on ideas of Bulaevskii, Buzdin and others and realized by Ryazanov et al. and others.

Born on 6th April, 1936 in Breslau

Study of physics at Humboldt Univ. Berlin in Göttingen and Hamburg, doctorate Univ. of Maryland (1963)

Full Professor of Physics, Frankfurt Univ. (1968-71)

Director at the Max Planck Institute for Solid-State Research (1974-93)

Emmy Noether Director and Scientific Member at the Max Planck Institut for the Physics of Complex Systems (1993-2007)

Member of the Leopoldina - National Academy of Sciences, Halle (since 1995)

Member of the Deutsche Akademie f. Technikwissenschaften (acatech) (since 2002)
